Monte Carlo Tree Search

Noah Syrkis

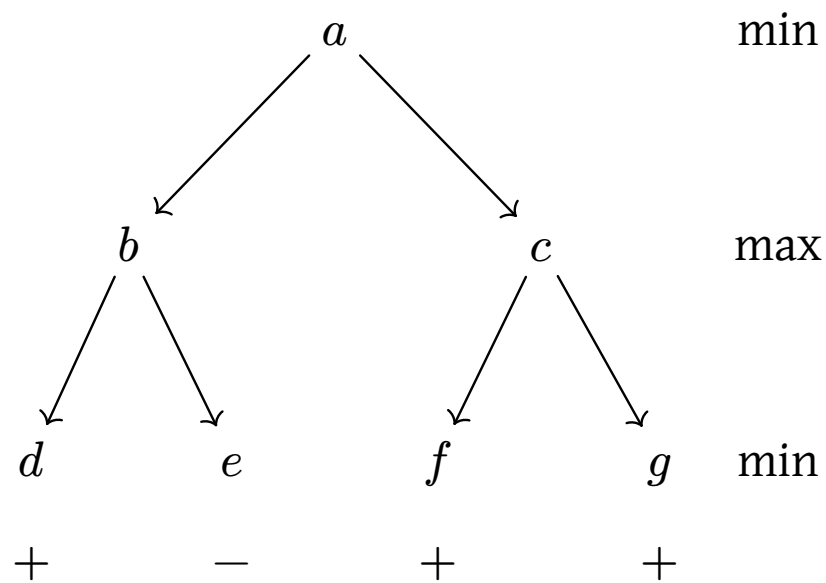
1 | Introduction

The future is a garden of forking paths [1]. Action a at state s_t yields a new state s_{t+1}. A different action a', however, might have yielded some different state s'_{t+1}.

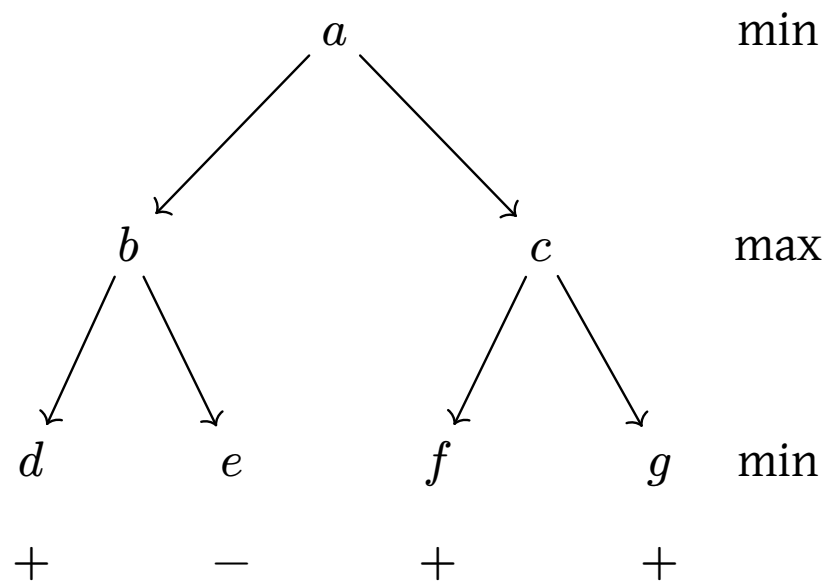
2 | Minimax

- Suppose we have a function that:
- given a state and an action returns a new state,
- and another that given a state returns who won
- What can we do?



2 | Minimax

- Suppose we have a function that:
- given a state and an action returns a new state,
- and another that given a state returns who won
- What can we do? Play perfectly and never loose



2 | Minimax

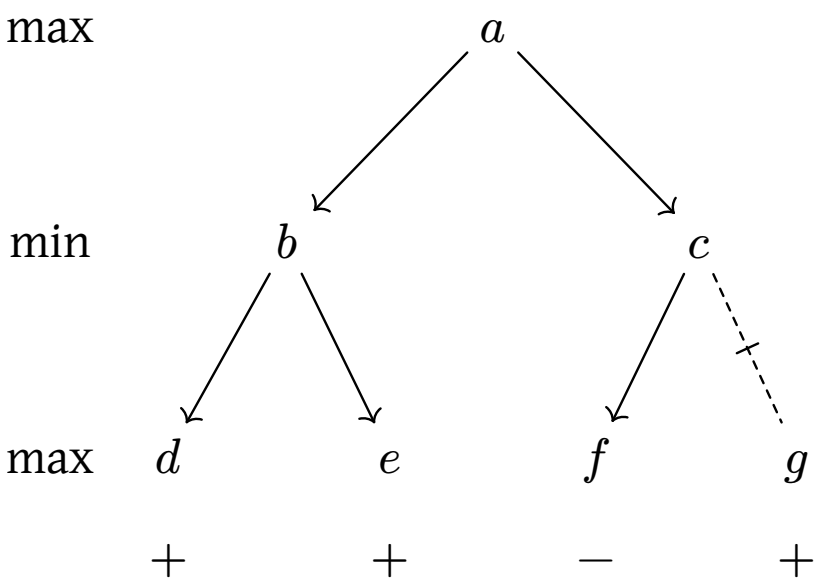
- We can win (or at least not loose) any game[1] by:
  1. Calling the minimax function for all actions
  2. Storing the values of each action in a list
  3. Taking the action with the highest value
- How can we do better? What are the issues?

Algorithm 1: minimax(state, maxim) $\rightarrow$ value

```
1 if node is terminal
2   | return the value of node
3 temp = −∞ if maxim else ∞
4 for each child of state
5   | value = minimax(child, not maxim)
6   | temp = (max if maxim else min)(temp, value)
7 return temp
```

[1] that is two player, winnable, deterministic, etc.

3 | $\alpha - \beta$ pruning



- Skip branches worse than current floor
- α and β refer to those precisely floors

3 | $\alpha - \beta$ pruning

- Algorithm 2 looks daunting but the idea is:
- Stop exploring paths you already know are bad

Algorithm 2: $\alpha - \beta$ pruning(node, maxim, α, β)

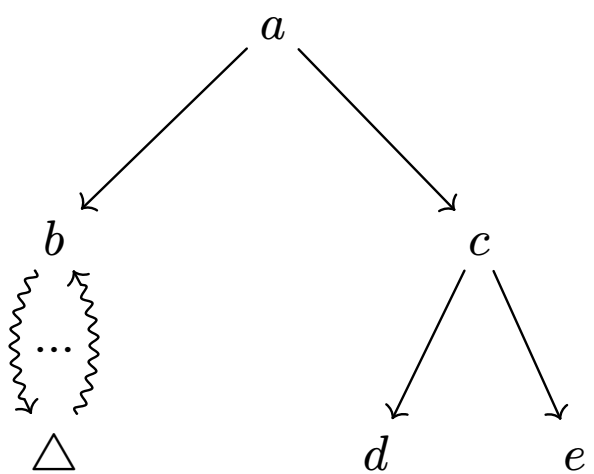
```
1  if node is terminal
2      return the value of node
3  bestValue = −∞ if maxim else ∞
4  condition = max if maxim else min
5  for each child of node
6      value = minimax(child, not maxim, α, β)
7      bestValue = condition(bestValue, value)
8      α = (condition(α, value) if maxim else α)
       β = (condition(β, value) if not maxim else
9
       β)
10     if α >= β; break
11 return bestValue
```

4 | MCTS

- We haven't actually looked at the board
- Humans don't mentally finish n games

4 | MCTS

- Monte Carlo (random) tree search [2]
- Core idea: sample from bottom of each branch
- How much to sample from each branch?
- How should we reach the bottom?



4.1 | Explore / exploit

- When do we exploit the best tool we have?
- When should we explore for a new tool?
- There is a good entropy based solution [3]

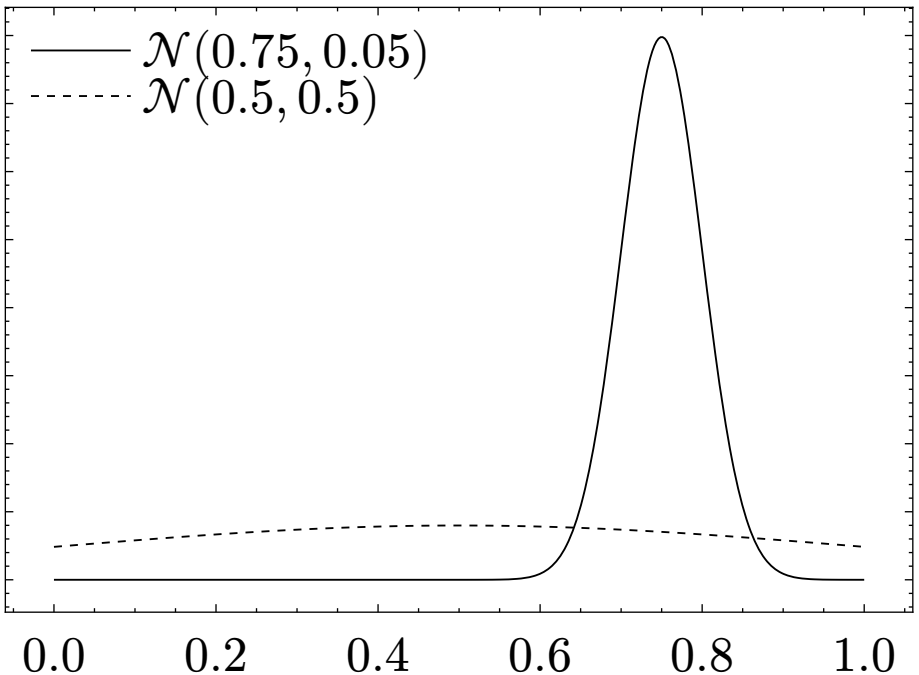


Figure 4: Which distribution would you sample from? Which is more likely to reach 1?

5 | Python

- You will see code that looks like Script 1
- In some games $s \neq o$, so we need seperate `obs`
- Multi player setup will have inner player loop

```
import gymnasium as gym
env = gym.game("tic_tac_toe")
state, done = env.init()

while not done:
  action = action_fn(state)
  state, done = env.step(state, action)
```

Script 1: Playing games in Python usually look something like this

5 | Python

- Some useful packages
- Understanding gymnasium is a must
- Get comfy with `.reset` and `.step`
- Sometimes `state` has a valid action mask!

`aigs`	package for our course
`gymnasium` [4]	Basic env package
`petting-zoo` [5]	gym for multiplayer
`pgx` [6]	parallel envs
`mlxp` [7]	experiment tracking
`parabellum` [8]	shameless plug
